

I worked on an AI backend system that connected FastAPI services with AWS tools like EC2, S3, IAM, and Amazon Bedrock to support multi-step AI workflow execution. The original design handled API requests synchronously, but this became unreliable when chaining multiple AI calls together, so I had to redesign parts of the workflow with better state tracking and error handling to improve consistency and scalability. I also adjusted the workflow structure to reduce failed requests and improve response reliability during testing. The project helped me better understand backend orchestration, API integration challenges, and how small architectural decisions can affect system performance at scale.
